

Assignment#1

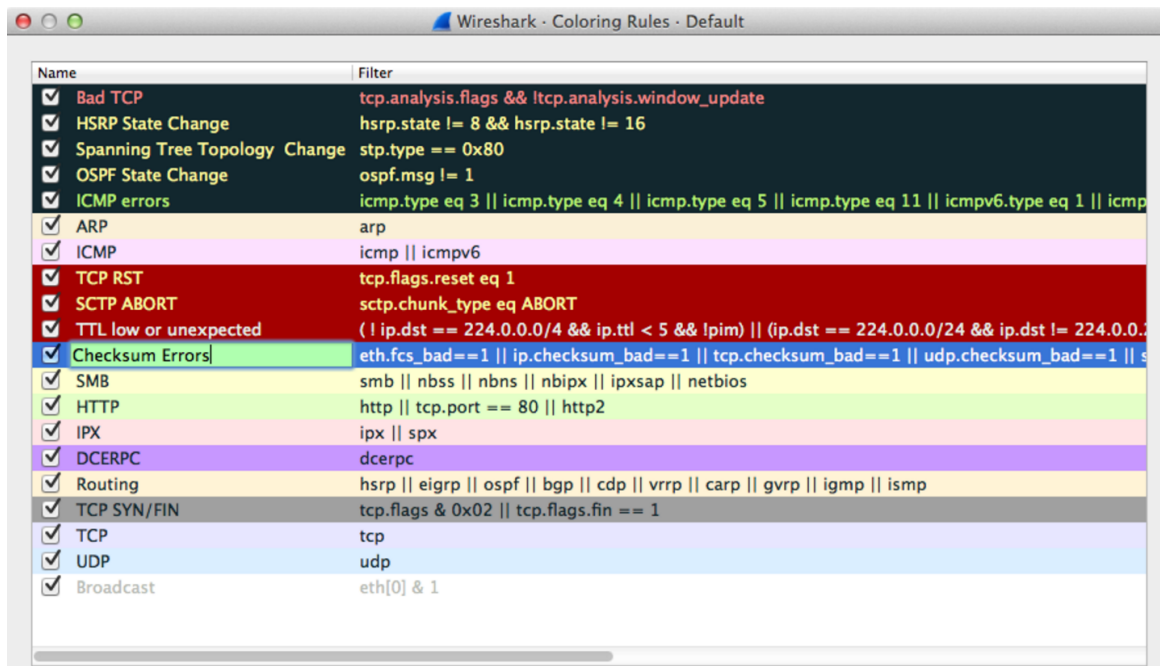

1) Wireshark is an open-source network traffic analyzer mainly used for monitoring the ongoing packets over a network for troubleshooting and managing its security and performance.

I attempted to connect www.google.com after running the Wireshark and the figure below is a sample of packets captured by the tool. As to be seen, each packets' Time, Source, Destination, Protocol, Length and Info attributes are observed by default.

No.	Time	Source	Destination	Protocol	Length	Info
817	29.365455	199.187.193.130	192.168.2.10	TCP	96	80→49751 [ACK] Seq=3101 Ack=6545 Win=24180 Len=0 [ETHERNET FRAME CHECK SEQUENCE INCORRECT]
818	29.435092	142.166.3.203	192.168.2.10	OpenVPN	1335	MessageType: P_DATA_V1
819	29.491646	52.5.26.156	192.168.2.10	TCP	495	[TCP Retransmission] 80→49750 [PSH, ACK] Seq=6849 Ack=5986 Win=136 Len=441
820	29.491689	192.168.2.10	52.5.26.156	TCP	66	49750→80 [ACK] Seq=5986 Ack=7290 Win=16425 Len=0 SLE=6849 SRE=7290
821	29.515525	199.187.193.130	192.168.2.10	TCP	1514	[TCP segment of a reassembled PDU]

Each color represents a different filter. The table below, presented in https://www.wireshark.org/docs/wsug_html_chunked/ChCustColorizationSection.html shows the rule represented by each color by default in Wireshark. Since I connected to google.com, we have mostly HTTP packets.

Clicking on a packet shows a sub-screen includes information about the headers for the packet. I clicked on the packet showed by the arrow in the first figure and observed the headers added by each layer. Transport Layer adds the TCP header shown below and it turns “DATA” to “TCP + DATA (segment)” where port numbers are seen.

```

Transmission Control Protocol, Src Port: 49804, Dst Port: 80, Seq: 0, Len: 0
  Source Port: 49804
  Destination Port: 80
  [Stream index: 28]
  [TCP Segment Len: 0]
  Sequence number: 0 (relative sequence number)
  Acknowledgment number: 0
  Header Length: 32 bytes
  Flags: 0x002 (SYN)
    000. .... = Reserved: Not set
    ...0 .... = Nonce: Not set
    .... 0... = Congestion Window Reduced (CWR): Not set
    .... 0... = ECN-Echo: Not set
    .... ..0. = Urgent: Not set
    .... ...0 = Acknowledgment: Not set
    .... ...0 = Push: Not set
    .... ...0 = Reset: Not set
    > .... ...1 = Syn: Set
    .... ...0 = Fin: Not set
    [TCP Flags: .....S.]
  Window size value: 8192
  [Calculated window size: 8192]
  Checksum: 0x70ea [unverified]
  [Checksum Status: Unverified]
  Urgent pointer: 0
  Options: (12 bytes), Maximum segment size, No-Operation (NOP), Window scale, No-Operation (NOP), No-Operation (NOP), SACK permitted
    > Maximum segment size: 1460 bytes
    > No-Operation (NOP)
    > Window scale: 2 (multiply by 4)
    > No-Operation (NOP)
    > No-Operation (NOP)
    > TCP SACK Permitted Option: True

```

Then, the segment goes to Network Layer where IP Header is added like below. In this header, we can see the source/destination IP addresses, Time-To-Live value (128) and Protocol ID (TCP). So, the segment is turned out a Datagram (IP Header + TCP + DATA).

```
Internet Protocol Version 4, Src: 192.168.2.10, Dst: 152.163.66.131
  0100 .... = Version: 4
  .... 0101 = Header Length: 20 bytes (5)
  ▷ Differentiated Services Field: 0x00 (DSCP: CS0, ECN: Not-ECT)
    Total Length: 52
    Identification: 0x10c9 (4297)
  ▷ Flags: 0x02 (Don't Fragment)
    Fragment offset: 0
    Time to live: 128
    Protocol: TCP (6)
    Header checksum: 0x4c22 [validation disabled]
    [Header checksum status: Unverified]
    Source: 192.168.2.10
    Destination: 152.163.66.131
    [Source GeoIP: Unknown]
    [Destination GeoIP: Unknown]
```

After that, the datagram/packet is sent to Data Link Layer and Ethernet header/trailer are added here. The datagram turns into a frame. Please see the figures below:

```
Ethernet II, Src: IntelCor_28:38:90 (ac:fd:ce:28:38:90), Dst: Actionte_b4:b8:b0 (4c:8b:30:b4:b8:b0)
  ▷ Destination: Actionte_b4:b8:b0 (4c:8b:30:b4:b8:b0)
  ▷ Source: IntelCor_28:38:90 (ac:fd:ce:28:38:90)
  Type: IPv4 (0x0800)

Frame 830: 66 bytes on wire (528 bits), 66 bytes captured (528 bits) on interface 0
  Interface id: 0 (\Device\NPF_{34FF98B6-C2F8-4B79-B2E0-3F2FFF0893C7})
  Encapsulation type: Ethernet (1)
  Arrival Time: Oct 24, 2016 21:33:44.985725000 Atlantic Daylight Time
  [Time shift for this packet: 0.000000000 seconds]
  Epoch Time: 1477355624.985725000 seconds
  [Time delta from previous captured frame: 0.002700000 seconds]
  [Time delta from previous displayed frame: 0.002700000 seconds]
  [Time since reference or first frame: 29.642706000 seconds]
  Frame Number: 830
  Frame Length: 66 bytes (528 bits)
  Capture Length: 66 bytes (528 bits)
  [Frame is marked: False]
  [Frame is ignored: False]
  [Protocols in frame: eth:ethertype:ip:tcp]
  [Coloring Rule Name: HTTP]
  [Coloring Rule String: http || tcp.port == 80 || http2]
```

In those figures, source/destination MAC addresses, Type Code (IPv4), Encapsulation Type (Ethernet), Arrival Time and Frame Length are observed. As to be seen, Wireshark is such a handy tool for network analyzers to sniff the packets over a network and reach the information carried by headers.

2) The java code , the input and output files are placed into assignment folder. Please note that, i fixed the number of bits of ASCII decimal vaules for each charachter as 7, which is the maximum digit as bit for an ASCII charachter. (127 = 1111111) The aim of fixing digit number is to make easier to convert back binary string to charachter string.

The example output for the code as follows;

```
Original Bit String :  
1000100110010111101001110000111000100000011100111001011110100101111100010101100100110010111011001101001110011110100011101001011111  
Stuffed Bit String:  
100010011001011110100111000011100010000001110011100101111010010111110000101011001001100101110110011010011100111110100011101001011  
Bit String After Discarded Zeros:  
100010011001011110100111000011100010000001110011100101111010010111110000101011001001100101110110011010011100111110100011101001011111  
Conveted Text:  
Detract yet_

Done
```

3)

a) Given a 12 - bit sequence 110100111101 and a divisor of 1011, find the CRC and the transmitted string.

$$M(x) = 110100111101$$

$$G(x) = 1011 = x^3 + x^1 + 1 \text{ (Degree of the reference is 3.)}$$

$$M'(x) = 110100111101000$$

$P(x)$ is the message to be sent. $R(x)$ stands for the remainder.

$$P(x) = M'(x) - R(x)$$

$$\begin{array}{r} 1011 \mid 110100111101000 \\ \underline{1011} \\ 1100 \\ \underline{1011} \\ 1110 \\ \underline{1011} \\ 1011 \\ \underline{1011} \\ 0001 \\ \underline{0000} \\ 0011 \\ \underline{0000} \\ 0111 \\ \underline{0000} \\ 1110 \\ \underline{1011} \\ 1011 \\ \underline{1011} \\ 0000 \\ \dots \\ \underline{} \end{array}$$

-> Remainder

There is no remainder so the message to be sent is;

$$P(x) = M'(x) = 110100111101000$$

b) Given a remainder of 101, a transmitted data unit of 10110011101, and a divisor of 1001, is there an error in the data unit. Show all steps

$$\begin{aligned} G(x) &= 1001 \\ P(x) &= 10110011101 \\ R(x) &= 101 \end{aligned}$$

If there is an error in the transmitted data, it should have a remainder of division to reference. Since transmitted data should be divisible to reference.

$$\begin{array}{r} 1001 \overline{) 10110011101} \\ \underline{1001} \\ 0100 \\ \underline{0000} \\ 1000 \\ \underline{1001} \\ 0011 \\ \underline{0000} \\ 0111 \\ \underline{0000} \\ 1111 \\ \underline{1001} \\ 1100 \\ \underline{1001} \\ 1011 \\ \underline{1001} \\ 010 \end{array}$$

010 --> Remainder

As you can see there is a remainder for P(x) that shows there is an error for this data. In order to find the correct data to be transmitted;

1) Reach the original message

$$\begin{aligned} P(x) &= M'(x) - R(x) \\ M'(x) &= P(x) + R(x) \end{aligned}$$

$$\begin{array}{r} P(x) \quad 10110011101 \\ R(x) \quad 00000000101 \\ \hline M'(x) = 10110011000 \end{array}$$

2) Find whether $M'(x)$ is divisible to $G(x)$ or not. If there is a remainder i will substract this remainder from the message, othervise $M'(x)$ is equal to the massage to be transmitted $P(x)$.

$$\begin{array}{r}
 1001 \mid 10110011000 \\
 \underline{1001} \\
 0100 \\
 \underline{0000} \\
 1000 \\
 \underline{1001} \\
 0011 \\
 \underline{0000} \\
 0111 \\
 \underline{0000} \\
 1110 \\
 \underline{1001} \\
 1110 \\
 \underline{1001} \\
 1110 \\
 \underline{1001} \\
 111 \quad \text{--> Remainder}
 \end{array}$$

I see that there is a remainder and this remainder helps me to find correct $P(x)$.

$$\begin{array}{rcl}
 P(x) = M'(x) - R(x) & M'(x) & 10110011000 \\
 & R(x) & 00000000111 \\
 \hline
 & P(x) & 10110011111
 \end{array}$$

The correct data to be tansmitted $P(x) = 10110011111$.

c) Implement the sending and receiving CRC protocol by writing program routines (functions/methods) for each of the following:

The java code is placed into submitted folder.

a. Given a bit string, compute the CRC remainder and generate the bit string to be transmitted.

The message to be sent is asked to user. The $G(x)$ is defined in the main folder. The example output for this question is represented as follows.

```
Enter message M(x):
1101011
1101011
_____ Assignment#2 - Q3 -c) - a) _____

Ref. No. : G(x) = 1101
Message: M(x) = 1101011
Transmitted Message: P(x) = 1101011010
```

In order to use the functions also for long bit strings i didnt convert the bit string to long or BigInteger. Since i wrote long division and xor operation functions to be used with bit string inputs.

b. Given a bit string with CRC remainder appended, divide by $G(x)$ and determine if the message is error-free.

The bit string is required to be entered by user. Example output for having a reminder :

```
_____ Assignment#2 - Q3 -c) - b) _____

Enter a bit string with CRC remainder appended:
1101011000
1101011000
There is an error! - Remainder:010
```

If the message is divisible by reference number:

```
_____ Assignment#2 - Q3 -c) - b) _____

Enter a bit string with CRC remainder appended:
1101011010
1101011010
There is no error.
```

d) Use the program in (c) to run the following experiment. Use the standard CRC-32 generator polynomial. Generate a random binary number of 1520 bytes. This will be your frame. Find the remainder (4 bytes). Now introduce a random burst error of length = 32 bits in the frame of 1524 bytes. Check to see if the error is detected.

For CRC-32 $G(x)$ is defined as:

```
String CRC32_g_X = "10000001001100000010001110110110111";
```

Since, it is binary representation for CRC-32 standard polynomial.

For the experiment, i provided information about the process for each 100 iteration. After 1000 loop is completed an summary information is represented as follows:

```
_____Assignment#2 - Q3 -c) - d) _____  
The experiment started!  
The 100. iteration is completed.  
The 200. iteration is completed.  
The 300. iteration is completed.  
The 400. iteration is completed.  
The 500. iteration is completed.  
The 600. iteration is completed.  
The 700. iteration is completed.  
The 800. iteration is completed.  
The 900. iteration is completed.  
The 1000. iteration is completed.  
Burst error length > 32: 330 Number of frames-error was detected: 312  
Burst error length = 32: 10 Number of frames-error was detected: 10  
Burst error length < 32: 660 Number of frames-error was detected: 660
```

As you can see, the algorithm is able to find all burst errors with length is equal to 32 or less. The rates for finding errors:

Burst Error Length	Number of frames	Number of frames in which error was detected	Rate for finding error
<32	660	660	%100
32	10	10	%100
>32	330	312	%94.5
